1. You can use ssh to connect to another device securely in remotely. You may need to change your listen address on “/etc/ssh/sshd_config”

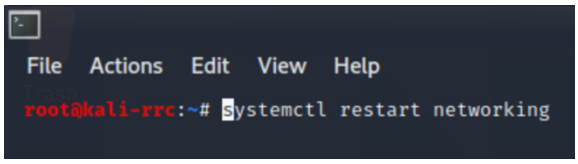

2. Continue editing the same file from “PermitRootLogin prohibit-password” to “PermitRootLogin yes”

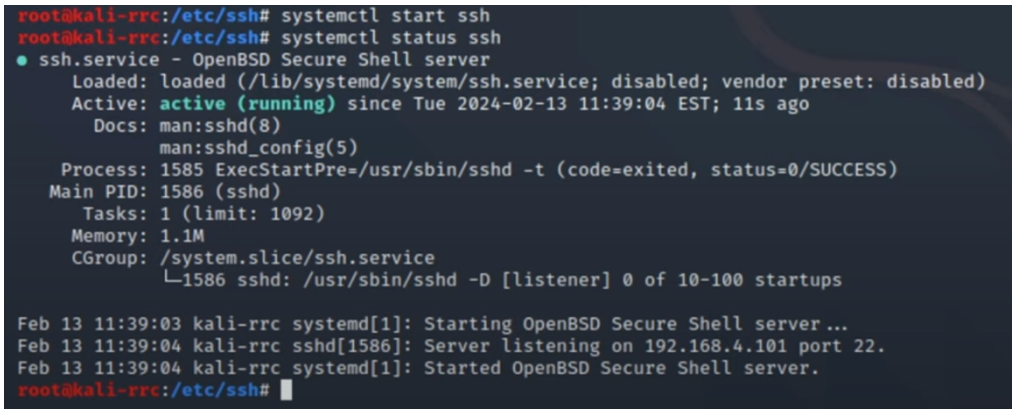

3. Change your current ip address of the machine on “nano /etc/network/interfaces/” and restart your networking using “systemctl”

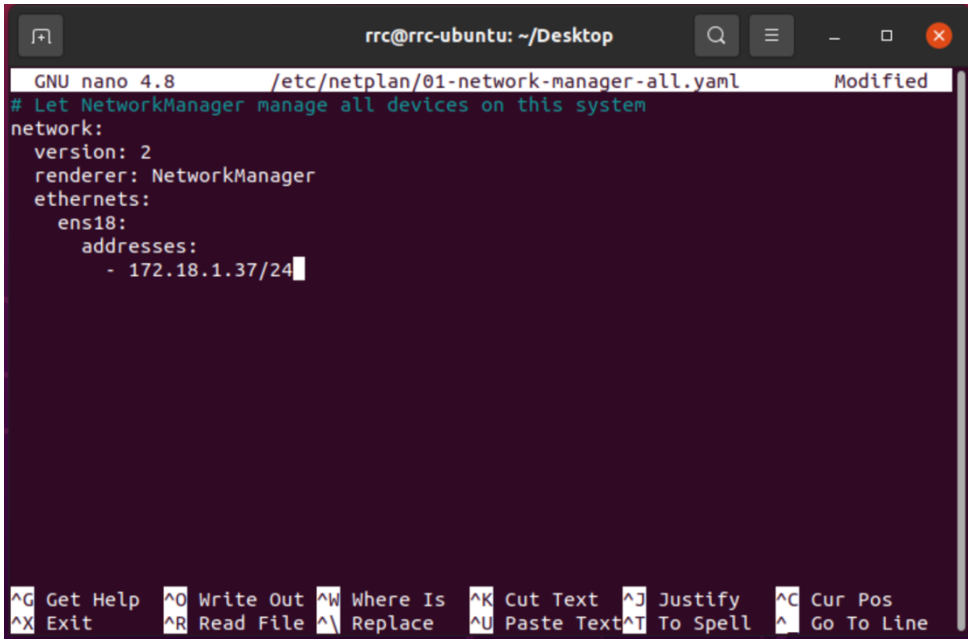

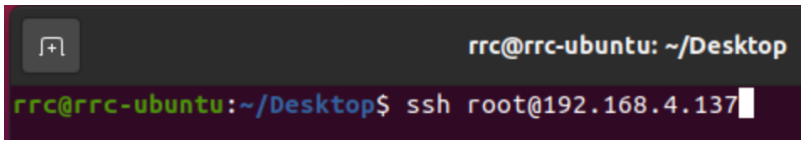

4. Restart your ssh server

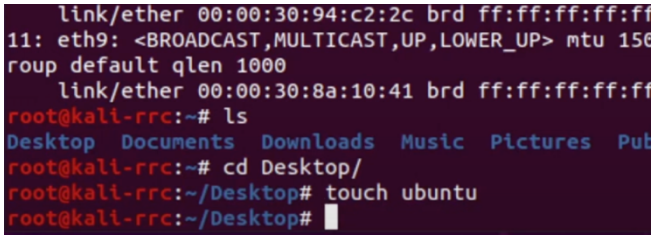

5. Change your ip address to the same network on the client side. Apply your changes with “sudo netplan apply” command

6. You can now ssh to the server with “ssh username@ipaddress”

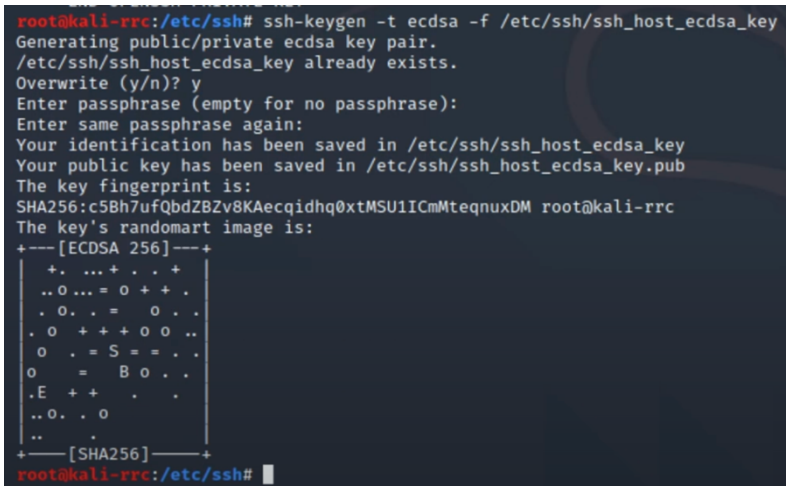

7. You are now securely connected to your other machine. Use the “exit” command to log out.

8. You can see where the public keys are saved in the client side in known host file.

9. In case of the keys being compromised in the server side, you can always generate new private and public key pairs using “keygen” command.

10. You may need to delete the known host file, in which the previous public keys are stored, in order to connect to the server side with ssh.
